

TURBOSTART HYDRODYNAMIC COUPLINGS

from 0.37 to 1470 Kw

TECHNICAL CATALOGUE

TURBOSTART

HYDRODYNAMIC COUPLINGS

New Turbostart s.r.l. was born in 1958, its corporate purpose is the production and sale of mechanical and hydraulic drives; the company has always been renowned for their new products reliability and professional service offered to clientele. It is a compact structure, efficient and always ready to solve the most varied problems of customers, succeeding in realizing even personalized products, guaranteeing, at the same time, rapidity and prompt deliveries. Over the years, it has always followed quality objectives, **officially recognized on several occasions all over the world.**

New Turbostart is in **continual development, both in Italy and abroad** (all continents) where it is selling hydrodynamic and hydromechanic couplings without slip at continuous running and 100% efficiency, couplings in cast iron for mines applications for powers ranging from 0,37 to 2.200 Kw, both for in line and pulley assembly, and also disk brake, drum brake, and all metal flexible couplings.

The administration and commercial offices are placed in Milan – Segrate, while production factory is located in Borgo Ticino – Novara, which is owned by New Turbostart and it covers 7.000 sq.m.

The factory is equipped with numerically controlled operating machines; processing of all particulars are carried out inside, as well as assembly and testing, whereas castings are made by skilled foundries in primary aluminium alloy

New Turbostart is certified, according to **UNI EN ISO 9001 – 2008** regulation, and it can supply couplings in according ATEX Certification.

The Hydrodynamic Coupling is a device of transmission of primary importance and has a large field of application. It is simultaneously a gradual starter and a stress eliminator and it is able to create in every moment and automatically an equilibrium between the motor and the transmission of the operating machine; therefore it eliminates every dangerous and unexpected overload and protects the motor and the transmissions as well.

PRINCIPLE OF OPERATION

The Turbostart Hydrodynamic Coupling consists of two impellers with symmetric vanes, a primary (pump) and a secondary turbine). The primary impeller driven by a motor sends a continuous flow of oil against the second impeller, transmitting therefore power to the other device.

Since the two impellers are opposite and have symmetric vanes, the result is that the Hydrodynamic Coupling has a perfect reversible function; also it is able to work horizontally, vertically or inclined (for sizes 18 - 19 - 110 P it's important to specify). The output speed of the standard Hydrodynamic Coupling is always lower than the input speed; the difference between the two speeds is commonly called "slip" and it is measured in percentage (%).

Under a constant torque the slip is maintained constant but if the output load increases, the secondary impeller (turbine) will slow down.

As a consequence there is an increase of liquid velocity into the fluid coupling and resulting in an increase of kinetic energy.

This increase of energy, pressing on the secondary impeller (turbine), balances the increased output load.

If this new output load is maintained constant and the motor is capable of supplying the equivalent power, a new equilibrium is established, characterised by a greater constant slip. On the contrary, at a decreasing output load, everything described above is inverted and the slip diminishes.

According to the slip we can determine the efficiency of the coupling and the value of power that is transformed into heat.

An accurate selection based on the effective power absorbed by the driven equipment determines the selection of the Hydrodynamic Coupling able to dissipate by natural ventilation the heat produced.

The Hydrodynamic Coupling with standard seals can normally withstand a maximum temperature of approximately 100° C and, with special seals, approximately 200° C.

ADVANTAGES

The Hydrodynamic Coupling, inserted into a transmission for starting up a high inertia machine controller by an asynchronous electric motor with Direct on Line Starting has the following advantages:

- **Eliminates the rigidity** of the mechanical transmissions and guarantees the flexibility of the Hydraulic transmission withstanding all the shocks, torsional vibrations and unexpected overloads, and protects the motor and driving machine.
- **Reduces peak current** during start-up. The electric motor rapidly reaches the operating speeds with low peak current.
- **Permits smaller motor sizes** according to the power demand of the driven machine.
- **Permits a high stop start** duty cycle even under load, sudden changes of direction and plug (reverse) braking.
- **Distributes the load in installations** where two or more motors are installed. The Hydrodynamic Coupling allows every motor to reach its own operating speed, automatically distributing load demand.

EXAMINATION OF THE BEHAVIOUR OF THE ELECTRIC MOTOR AND THE HYDRODYNAMIC COUPLING DURING THE START-UP

To fully realize the above mentioned advantages, it is necessary to select the correct hydrodynamic coupling. Let us consider the behaviour of both the motor and hydrodynamic coupling when the two items are working together, from the moment of the start to full speed.

Examining the diagram Torque (C) vs Speed (v)

Fig. 1 on which the curves:

M - torque curve of a direct start (DOL) asynchronous electric motor.

I - Current vs Speed (v).

Following the curve M during starting (when $v = 0$) we notice that the available torque C_a is approximately 1.5 times the rated torque C_n on DOL starting, and approximately 0.6 times C_n on Star Delta Starting (C_{st}).

Normally the motor operates at speed n_1 where the rated torque C_n is equal to the working torque.

It should be noted that the motor produces maximum torque C_m of 2.5 times the rated torque C_n at the speed n_m (90% of rated speed).

Following curve "I" we note that the current at start I_a is 5-6 times the nominal rated current.

At this stage the motor temperature is rather high.

At speed n_M the current I_M is about 3 times the rated current I_N and the temperature of the motor is noticeable reduced; also the elevated speed of the motor facilitates its own cooling.

Therefore, during startup the motor must reach speed n_M as quickly as possible in order to avoid overheating, and to deliver maximum available torque to the driven machine.

If there is an exceeding torque C_e , comparatively low, and no hydraulic coupling is used, the duty cycle will be quite slow, and this could result in damage being done to the motor, unless the motor has been adequately oversized.

Fig. 1

VARIATION OF START CONDITIONS UTILISING THE HYDRODYNAMIC COUPLING

Let us consider a coupling having a slip $S = 100\%$ crossing the curve M at the point nearest to the maximum torque (fig.1).

Since a speed $v = 0$ the coupling transmits no torque, the electric motor has all torque C_a available for the rotor acceleration.

During the acceleration the oil moved by the pump element of the hydrodynamic coupling, gets in greater quantity into the circuit, acting more and more on the turbine element connected to the driven machine. As soon as the torque produced by the coupling overcomes the resisting torque, the driven machine starts moving.

At this stage the torque available for the acceleration of the driven machine is $C_M - C_n$ therefore of higher value of torque C_n , which is the starting torque available if no hydraulic coupling is used.

It is important to note that the availability of the high accelerating torque is obtained at a current I_M which is approximately half of the value of the current I_a , corresponding to the acceleration torque C_a and the heating of the electric motor is reduced.

As the oil enters the circuit, the difference of speed between the motor and the driven machine diminishes, until an equilibrium is reached between the dragging torque and the resisting torque when the motor reaches its operating speed n_1 .

Then the coupling will work at normal slip s .

THE BEST USE OF MAX MOTOR TORQUE

If the curve of motor torque M meets the curve of coupling torque S before the point of max value, it means that the selected coupling is overdimensioned, or there is too much oil inside. Under this condition the rotor has difficulty to accelerate and the hydrodynamic coupling rotates without being able to accelerate the driven machine.

To obviate the inconvenient it is necessary to drain some oil to get a lower slip curve of the hydrodynamic coupling.

Instead, if the curve meets after the point of maximum torque value, it means that the selected coupling is underdimensioned.

It is to keep in mind that the slip of a coupling-filled with a special quality of oil- is a function of the rotating speed, of the resisting torque and of the quantity of oil.

Moreover, if a coupling is requested to operate at different speeds, at equal slip the power and torque transmitted are directly proportional to the cube and square of the requested speeds.

The standard Turbostart Hydrodynamic Coupling can be fitted with a partial oil drainage device, allowing the best use of the maximum motor torque (page 20).

USE OF THE HYDRODYNAMIC COUPLING WITH DIESEL ENGINE

The diesel engine has an unstable torque curve and a minimum operating speed below which the engine stalls.

When the stall is caused by overloads, the use of the hydrodynamic coupling eliminates the problem and offers the following advantages.

- **Stabilizes the operation of the engine.** Considering the curve M' (fig. 2) obtained with a partial supply, we reach a point of equilibrium P_4 when the engine output torque at a speed of V_1 , is equal to the resistive torque transmitted by the hydrodynamic coupling with a slip $s = \%$.

At increasing of resistive torque the point of equilibrium is transferred to P_3 , at an engine speed V_3 and the coupling gradually reaches a 100 % slip. At this stage the governor of the diesel engine increases the speed to V_2 , and the torque to a new point of equilibrium C_1 , is obtained with an output torque supplied by the coupling with a slip of 5 %.

These variations are controlled by the hydraulic coupling, which maintains the engine very stable.

- **Facilitates the starting of the engine.** On starting and at low input speed, the hydrodynamic coupling does not oppose to the engine which is free to reach the rated speed. When it is inserted between the engine and a mechanical clutch, noticeably it reduces clutch wear.

- **Prevents the engine stall.** When the driven torque is higher than the supplied torque the slip of the coupling goes to 100% maintaining the engine a speed higher than the stall speed.

Obviously at this condition the driven machine should be disengaged to avoid build up of temperature into the hydrodynamic coupling

- **Absorbs torsional vibrations.** This feature is very important when controlling machines operating at frequent load variations.

Knowing the input power and speed of the coupling, we use the diagram on page 5 (to select the right coupling).

For a continuous operation it is enough to consider the power demand of the driven machine.

For higher start-stop duty cycle and if the selection point (input speed/power) is close to the high limit of the band that defines the characteristics of the coupling, we have to select the net size up of the coupling and use high temperature seals.

The oil level must be adjusted to not overload the motor during the start.

PERFORMANCE CALCULATION AND CHECK

Data

- Speed of driven machine: n_2 (RPM)

- Inertia: I (kgm^2) $\left(\frac{PD^2}{4}\right) \text{ o } \left(\frac{GD^2}{4}\right)$

- Absorbed power: P_a (kW)

- Input speed: n_1 (g/min)

- Ambient temperature: T ($^{\circ}\text{C}$)

Inertia of driven machine to motor shaft = kgm^2

$$I_{n1} = I \left(\frac{n_2}{n_1}\right)^2$$

Coupling output speed = RPM.

$$n_g = n_1 - s \quad (s = \text{slip})$$

You can get it from diagram input speed according to the absorbed torque C_c (Nm) or by using an average value from 5 to 3 (from small to big units)

$$\text{Motor power} = \text{Kw} \quad P_m = \frac{I_{n1} \cdot n_1^2}{9.12 \cdot 10^4 \cdot t_a}$$

t_a = startin time

$$\text{Nominal torque} = \text{Nm} \quad C_m = \frac{9550 \cdot P_m}{n_1}$$

$$\text{Torque absorbed by driven machine} = \text{Nm} \quad C_c = \frac{9550 \cdot P_a}{n_g}$$

$$\text{Starting torque} = \text{Nm} \quad C_a = 1,6 \cdot C_m - C_c$$

For coupling with R reduce from 1,6 to 1,4

$$\text{Starting time} = \text{sec.} \quad t_a = \frac{n_g \cdot I_{n1}}{9,55 \cdot C_a}$$

$$\text{Temperature generated during acceleration} = \text{K cal.} \quad Q = \frac{n_g}{10^4} \left(\frac{I_{n1} \cdot n_g}{76,5} + \frac{C_c \cdot t_a}{8} \right)$$

$$\text{Thermal capacity of the coupling} = (\text{Mo}) \quad (\text{K cal} / ^{\circ}\text{C})$$

Add metal + oil (see table)

THERMAL CAPACITY

Coupling size	Metal K cal/ $^{\circ}\text{C}$	Oil K cal/ $^{\circ}\text{C}$
155	0.75	0.43
190	1.16	0.92
220	1.63	1.26
240 N	2.24	1.73
275 N	3.20	2.10
355	5.60	3.60
400	7.20	4.30
445	12.1	6.60
18	12.1	6.60
19S	17.4	12.3
19	17.4	12.3
110	33.7	23.7

Increase of temperature during accaleration = ($^{\circ}\text{C}$)

$$T_i = \frac{Q}{M_o}$$

Factor K:

Fattore K ricavabile dalla tabella seguente:

Increase of temperature during starting running = $^{\circ}\text{C}$

$$T_{\Delta} = 2,4 \cdot \frac{P_a \cdot s}{K}$$

Final temperature = $^{\circ}\text{C}$ $T_t = T + T_i + T_{\Delta}$

T : ambient temperature

T_t : has to be lower than 110°C

For higher temperature and till 175° , special seals are necessary.

Minimum working cycle for hour = sec

$$t_w = 10^3 \cdot \frac{Q}{T_i \cdot K}$$

Maximum working cycle for hour:

$$A = \frac{3600}{t_a + t_w}$$

IMPORTANT: For version PC-R, when mounting is vertical axis, it is essential for the coupling to be placed under the motor.
The weights and dimensions can be modified.

COUPLING SIZE	F		N° Grooves		Ø Pr	Y		X	Weight Kgs
155	56		2A - 2SPA		70 - 80 - 100	12		15	1 ÷ 1,3

445	180		10 B - 10 SPB		250*	31		19	25 ÷ 45
					300*				

During start the hydrodynamic couplings with the standard oil level do not allow the produced torque to increase above 200% of motor rated torque.

It is possible to reduce this limit further without reducing the quantity of oil by using the device R which, when the coupling is stationary, collects some of the oil from the circuit.

During start the low level of oil facilitates the fast acceleration of the electric motor and causes the coupling to transmit a very limited torque (phase 1).

Subsequently the oil contained in the tank of the device R is gradually brought into the circuit by the internal movement through the calibrated holes of the diagram situated between the device R and the coupling (phase 2).

When the driven machine is up to operating speed, all the oil is into the coupling which is now capable to produce the maximum work (phase 3).

With the device R the starting torque can therefore be reduced to 140% of the rated motor torque.

The use of the option is suggested for the starting of:

- Machines with high inertia
- Machines driven at high speed
- Machines that require soft starting.

All the Hydrodynamic Turbostart models can be fitted with the device R (VD excepted).

Oil level at rest (phase 1)

Oil level at startup (phase 2)

Oil level during work (phase 3)

Acceleration torque of Turbostart Hydrodynamic Coupling

- A with standard circuit
- B with partial draining device

Part numbering system

On request hydrodynamic and hydromechanic Turbostart couplings can be supplied with protecting devices for the protection of the coupling against possible extended overloads.

In case of extended overloads the high slip produced causes the oil temperature to rise triggering the protective device which can be used to stop the machine or give an acoustic or visible alarm.

THERMAL TRIGGER DEVICE

At a certain predetermined temperature the little piston leaves its seat and acts on a limit switch, stopping the machine or giving a warning signal. The device is reset by replacement of this trigger plug.

FUSIBLE PLUG DEVICE

At the selected temperature(145°C or 175°C) the fusible material of the plug melts and the oil gets out of the coupling and causes the transmission stall

Fusible plug at 145° or 175° on request

INSTALLATION

- Lubricate the surfaces to be assembled with oil or antiseize grease.
- Check that the connection to the driven shaft is slightly loose but precise to avoid vibrations.

Model with pulley P

- After having checked the correct balancing, assemble the pulley on the hydrodynamic coupling.
- Secure the coupling on the shaft with the fixing screw B and washer C (fig. 1)
- Check pulley alignment and belt tension to avoid bearing damage.

Draining device
with through hole

Fig. 1

In line model L

- Remove the flexible coupling (L/E) or remove the output shaft (L/MU).
- Secure the hydrodynamic coupling on the shaft with the fixing screw B and washer C (fig. 2)

and testing with the guage every 90°, the T.I.R. difference should be within 35 ' of one angular degree.

A good alignment prevents premature wear of the flexible coupling element.

Models with the delay chamber device "R"

- Proceed as per models P or L. The coupling is fixed on the shaft with the fixing screw through the hole in the device (fig. 1)

DISASSEMBLY

- Remove the fixing screw and washer (B, C) and with the puller dislocate the coupling from the shaft (fig. 3).
- Arrest the housing with a spanner on nut ring and screw the puller.

(parts 4 - 5 - 6 are supplied on request)

PULLER

- Refit the flexible coupling on the driven shaft (L/E) or reinstall the output shaft (L/MU)
- Align the electric motor to the machine leaving 2 ± 3 mm. gap in the flexible coupling (L/E)
- Check the radial alignment of the flexible coupling by making sure that the alignment of the external machined surfaces are within 0,5 mm. maximum using a rule.
- Check with a feeler guage the angular alignment of the flexible coupling by turning the coupling 360°

OIL FILLING

The Turbostart hydrodynamic coupling are normally supplied complete with oil filling and ready to put into operation. To refill the oil during maintenance, proceed as follow:

- Arrange the coupling with horizontal axis;
- Place the arrow marked on the casting at 12 o'clock position (rotating towards the top) the filler plug will be at an inclination in relation to vertical according to the angle inclined in the table below and fig.2.

Fill oil through one of the filler parts until the oil begin running out, paying attention that no air bubble is present. The coupling have never to be totally filled in order to avoid damages to the seals due to the inner pressure.

For the oil quantity required please refer to the table below.

Recommended oils SAE 10 :

Agip OSO 32	Fina Hydran 32
BP Energol HLP 32	Mobil DTE 24
CHEVRON Hydraulic oil EP 32	SHELL Tellus 32
ESSO NUTO H 32	Total Azolla 32

For special conditions (temperature, ambient) please contacts your Turbostart distributor.

OPERATION

The maximum operative temperature should not exceed 90°C.

In heavy duty working cycle, it is possible to exceed this value by using special seals.

High operating temperature can be caused by:

- insufficient oil filling
- high absorbed power, due to an extended overload
- long starting time and too frequent starts
- high ambient temperature
- insufficient air ventilation due to carter. Adequate ventilating apertures should be provided.

MAINTENANCE

After few hours of operation, check the tightness of bolts and screws.

From time to time check that no oil leakages are present. Check the oil level once a month.

The oil should be changed every 4000 hours of operation or every 12 months.
