JAURE® COUPLINGS AND POWER TRANSMISSION SOLUTIONS

We are a leading supplier of couplings and power transmission solutions. Experience, manufacturing expertise, innovation and close cooperation with leading international companies enable us to provide customized solutions to our customers.

For over 50 years, we have developed couplings for the most demanding applications in marine, wind, energy, steel, railway and paper industries among others.

We have a broad range of manufacturing capabilities, particularly with respect to power and speed. We continue developing new products for future challenges.

The integration of Kop-Flex® and Jaure® coupling products has added to our ability to apply technical expertise in providing answers, products and services to our customers for their many varied applications globally.

BARFLEX® BARREL COUPLING INTRODUCTION

Jaure® TCB® and TCB-HD barrel couplings were developed back in the 90s as the optimum coupling solution for hoisting applications. The advantage of these couplings compared to gear couplings is that they can absorb high misalignment and have less bending stress wear, and hence they provide longer life.

The NEW Barflex® TCBR barrel coupling is an upgraded version of the original barrel coupling. It is 100% interchangeable with the TCB and TCB-HD coupling ranges and provides the following benefits:

New Barflex® TCBR Coupling Design Features

- **ABOUT 10% HIGHER TORQUE CAPACITY**, allowing a more favorable size selection and thus an important cost saving.

- **ASSEMBLY TIME REDUCTION.**

- **INCREASED AXIAL MISALIGNMENT TOLERANCE.**

- **IMPROVED VISUAL WEAR INDICATOR:**

Easier to read the wear.

APPLICATION

JAURE® Barflex® TCBR barrel coupling is specially designed for installation in cranes & hoisting applications to connect the cable drum with the gear box output shaft. This coupling is also used in steel mills, winch and conveying applications as well as in stackers and reclaimers.

Barflex TCBR coupling satisfies the requirements described by German Steel & Iron Standard (Stahl-Eisen-Betriebsblatt) SEB 666212, Part 5, issued in March, 1992.

A generalized layout of lifting mechanism is shown in Fig. n° 1. The electric motor shaft is coupled to gear box input shaft by means of high speed flexible coupling, while a TCBR barrel coupling is installed in between gear box output shaft and the cable drum flange.

Fig. n° 1.
Mounting of a barrel coupling in a lifting mechanism.

The typical arrangement for connecting the cable drum with the gear box output shaft is shown in Fig. n° 2 and Fig. n° 3.

When the gearbox output shaft is rigidly connected to drum flange in a lifting mechanism (Fig. n° 2), this originates a statically indeterminate case. This type of arrangement requires special care and considerable amount of time for doing the initial alignment, which is difficult to achieve in practice. Moreover, mounting inaccuracies, as well as deformation in structure and wear in moving part, lead to generate enormous additional forces which result in fatigue failure of shaft, driving gear or bearings.

It is highly recommended to use barrel coupling for installation between gear box output shaft and cable drum flange. As shown in Fig. n° 3, the barrel coupling acts as an articulated joint, allowing limited axial and angular misalignment. Thus, making the connection statically determinate and helping to avoid high bending moment loads which can cause fatigue failure of shaft, driving gear or bearings.

Fig. n° 2.
Rigid mounting of gearbox-drum connection. Support at three points.

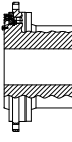

Fig. n° 3.
Mounting with barrel coupling.

Since the barrel coupling allows a limited axial displacement it is imperative to use a self-aligning roller bearing fixed at the opposite end of drum shaft in order to withstand the axial forces that may be generated.

BARFLEX[®]

BARREL COUPLING

DESCRIPTION

The barrel coupling consists of a sleeve which is provided with semi-circular toothing around its internal diameter and a hub which is provided with similar kind of toothing over its external diameter. A series of specially designed spherical hardened barrels are inserted inside the hub and sleeve pockets.

The torque is transmitted from hub to sleeve through these self-aligning barrels, which act as a floating member. The internal space between the hub and sleeve pockets, in addition to the convex shape of the barrels with a specially designed crowning radius allow the coupling to take angular misalignment up to 1° and an axial displacement in the range of ±3mm to ±12mm. See product data on page 18-19.

The sleeve is provided with two diametrically opposite flat faces on flange to establish a connection between the sleeve flange and drum flange. The torque is transferred partially in friction through a series of high tensile bolted connection between the sleeve flange and drum flange and in compressive mode between the flat faces.

The axial movement of barrel is restricted with a retainer ring & seeger ring.

The external cover and sleeve are provided with specially designed seals to avoid lubrication losses by assuring perfect integrity of lubrication zone and avoiding penetration of foreign particles.

The barrel design is appropriate to minimize the contact pressure under large radial loads and minimize the effect of alternating bending stress on the toothing. The sliding velocity is kept to minimum under the misalignment compensation which helps to minimize the wear in the hub and sleeve pockets.

The teeth design is robust and in semi-circular shape. The height of teeth is small compared to its width at the bottom. In addition to this, due to the effect of a “crush polishing” of the hardened barrel on the tooth profile, its wear resistance is appreciably improved.

Barrel couplings are prone to wear during usage. Wear is a common phenomenon which occurs due to sliding and rolling actions of the barrel over the coupling hub and sleeve pocket interface. Due to this, there is a relative displacement between the hub and sleeve. This displacement as a function of wear is detected by means of a mechanical wear indicator. The coupling should be replaced when the predefined wear limit is reached.

The torque and radial load rating of new Barflex® TCBR coupling is improved significantly. Extensive research in the field of design optimization, Finite Element Analysis, and rigorous testing enabled us to improve the performance of newly designed TCBR coupling.

New TCBR coupling is equipped with modern mechanical wear indicator system. The specially designed pointer/Indicator is mounted on cover which moves relative to the axially mounted square pin on the hub as a function of wear, permits control of internal wear of the tothing without the need to disassemble any part of the coupling. The same indicator also controls the axial position of the sleeve relative to the hub. Optionally, an electronic wear indicator can be installed for remote control (for more details see page 24).

TCBR couplings can be used at -30°C to 70°C temperature range. For other temperatures, please contact the Jaure® couplings engineering team.

The Barflex TCBR coupling design is verified by Finite Element Analysis (see Fig. n° 5) and validated by performing in-house test.

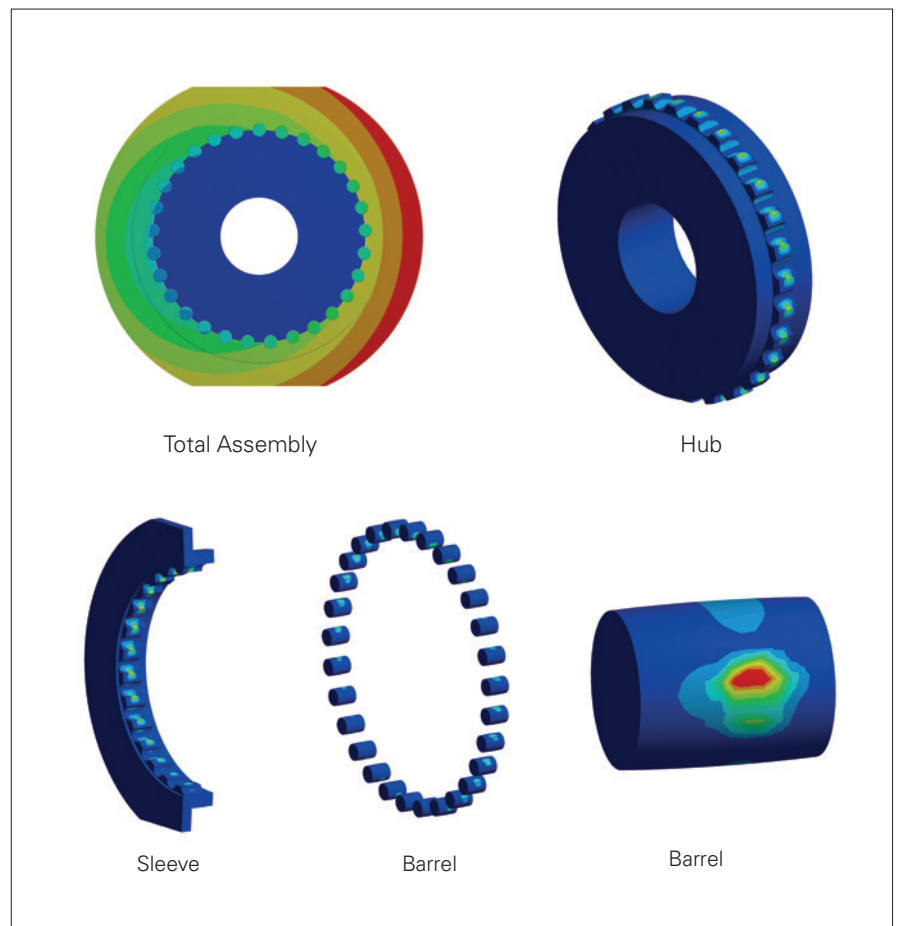

Fig. n° 5

BENEFITS OF USING BARREL COUPLINGS INSTEAD OF GEAR COUPLING

The mounting space required for barrel coupling is significantly lower as compared to a gear coupling. A barrel coupling is narrower than the equivalent gear coupling, and it is partially positioned inside the drum.

Due to the profile of barrel and shape of hub and sleeve pocket, barrel couplings are subjected to much lower bending stress on the root of the teeth. Therefore, increased safety factor is obtained against bending and peak radial loads.

The radial load in barrel coupling is better distributed due to the increased contact area (Fig. n.º 6) and hence the life of the coupling is increased.

Below graph (Fig. n.º 7) shows the comparison of stresses in barrel coupling and gear coupling under the radial load. This radial load is even better distributed with coupling wear in barrel coupling.

Fig. n.º 6
Technical modifications reserved. $b_1 \geq 2 \cdot b_2$

Fig. n.º 7
Bending stress in the coupling for a given radial load (%).

COUPLING SELECTION

Coupling selection requires the validation of:

- 1/ Coupling maximum permissible torque T_{c_MAX}
- 2/ Coupling admissible radial load F_r
- 3/ Connection between coupling and shaft

1. COUPLING MAXIMUM PERMISSIBLE TORQUE T_{c_MAX}

Selection torque T will be the maximum of the values calculated in two ways: based on the installed power (P_i) or based on the consumed power (P_c).

Coupling maximum permissible torque T_{c_MAX} rating must be over this selection torque T .

1.1 Based on installed power (P_i)

The calculation based on the installed power of the motor (P_i) requires knowing the value of the drum turning speed (n) and applying the correction of the operating factor (K_1) according to the cable transmission group.

①

$$T = 9550 \cdot \frac{P_i}{n} \cdot K_1$$

WHERE:

P_i (kW) = max. installed power of the motor

n (rpm) = drum turning speed

K_1 = operating factor (see Table n°1)

Table n.° 1. Operating factor K_1 , according to cable transmission group

GROUP DIN 15020	1B m	1A m	2 m	3 m	4 m	5 m
GROUP FEM (1970)	IB	IA	II	III	IV	V
GROUP FEM (1987)	M1, M2, M3	M4	M5	M6	M7	M8
GROUP BS 466 (1984)	M1, M2, M3	M4	M5	M6	M7	M8
Operating factor K_1	1, 12	1,25	1,40	1,60	1,80	2

1.2 Based on consumed power (P_c)

The formula for the calculation of the torque based on the consumed power of the motor (P_c) is the same as the previous case, but for knowing the consumed power of the motor, values of the drum static pull (F_p) and the drum lifting speed rate (V_r) are required. The drum lifting speed is calculated with the turning speed (n) and the drum diameter (D):

Different examples of hoist tackle configurations.

Fig. n.º 8.
Twin hoist, 2 sheaves. Double line to drum.

Fig. n.º 9.
Twin hoist, 4 sheaves. Double line to drum.

Fig. n.º 10.
Hoist, 2 sheaves. Single line to drum.

Fig. n.º 11.
Hoist, 4 sheaves. Single line to drum.

$$\textcircled{2} \quad T = \frac{P_c \cdot 9550}{n} \cdot K_1$$

$$\textcircled{3} \quad P_c = \frac{F_p \cdot V_r}{60000}$$

$$\textcircled{4} \quad V_r = \pi \cdot D \cdot n$$

WHERE:

P_c (kW) = max. power consumed by the motor

F_p (N) = drum static pull, including cable and pulley efficiency (see Equation 6)

V_r (m/min) = drum cable lifting rate

n (rpm) = drum turning speed

D (m) = drum pitch diameter

K_1 = operating factor (see Table n.º 1)

The determination of the Drum Static Pull (F_p) is based on the Max load on the hook (Q), the weight of the hoist tackle and cables (G), transmission ratio (i_r) and the operating factor of drum and hoist (K_2).

The transmission ratio (i_r) depends on the hoist tackle configuration. Examples on figs 8, 9, 10 and 11 for different configurations.

$$\textcircled{5} \quad F_p = \frac{Q + G}{i_r \cdot K_2}$$

WHERE:

Q (N) = max. load on hook

G (N) = weight of hoist tackle and cables

K_2 = operating factor of drum and hoist tackle efficiency (see Table n.º 2)

i_r = transmission ratio = $\frac{\text{Total number of lines}}{\text{Number of lines leaving the drum}}$

Table n.º 2. Operating factor K_2 according to drum and tackle efficiency

Hoist tackle reduction i_r	2	3	4	5	6	7	8
K_2, with bronze bearings	0,92	0,90	0,88	0,86	0,84	0,83	0,81
K_2, with ball bearings	0,97	0,96	0,95	0,94	0,93	0,92	0,91

2. COUPLING ADMISSIBLE RADIAL LOAD F_r

Selection of radial load calculation is based on static pull of the drum (F_p), the weight of the drum with cables and parts of the coupling (w) and the geometry of the drum.

Coupling radial load F_r rating must be over this selection radial load.

For systems with double cables to the drum (fig. 8 and fig. 9) formula is:

$$\textcircled{6} \quad F = \frac{F_p}{2} + \frac{w}{2}$$

And for systems with a single line to the drum (fig. 10 and fig. 11):

$$\textcircled{7} \quad F = [F_p (1 - \frac{b}{l})] + \frac{w}{2}$$

WHERE:

F_p (N)= Static pull of drum, including cable and pulley efficiency

b (mm)= Shortest possible distance from cable in drum to the geometric centre axis of barrels in the coupling.

l (mm)= Distance between drum supports

w (N)= Own weight of drum with cables and parts of the coupling

2.1. Corrected radial load F_A

When selection torque is below coupling torque $T_{C\text{MAX}}$ and selection radial load is greater than the admissible radial load F_r , it is possible to increase the coupling admissible radial load by considering the operating factor (K_1) according to the cable transmission group using below equation:

$$\textcircled{8} \quad F_A = F_r + \left(\frac{T_{C\text{MAX}} - T}{K_1} \right)$$

WHERE:

F_A = Corrected radial load (N)

T = Selection Torque (Nm)

F_r = Coupling max radial load (N)
(See Table at page 18-19)

K_1 = operating factor (see Table n.º 1)

$T_{C\text{MAX}}$ = Coupling maximum torque (Nm)
(See Table at page 18-19)

The reverse procedure, i.e. to increase the max. permissible torque if the radial load is not fully used, is not allowed.

3. CONNECTION BETWEEN COUPLING AND SHAFT

There is a limitation in the maximum shaft diameter allowed in a coupling size. The diameters shown in the table of page 18 are valid for shaft with keyways according DIN 6885/1.

If a different connection is used such as splines shafts according 5480, interference connection, or other connection, validation is required. Please contact the Jaure® Couplings Engineering Department.

SELECTION EXAMPLE

As a coupling selection example, the crane has the following characteristics:

Q = 300000 N (useful load to be lifted)	K₁ = 1.8 (Group IV)
G = 10000 N (hoist weight)	K₂ = 0.95 (Drum and hoist efficiency)
w = 14000 N (weight of drum and cables)	b = 400 mm (distance between cable and coupling)
P_i = 30 kW (motor power)	l = 1200 mm (drum length)
n = 8 rpm (drum turning rate)	d = 200 mm (gearbox output shaft, with key)
D = 800 mm (drum diameter)	
i_r = 4 Hoist reduction	

And the installation layout is the one shown in Fig. 10:

1. COUPLING MAXIMUM PERMISSIBLE TORQUE T_{C MAX}

1.1 Based on installed power (P_i)

$$T = \frac{9550 \cdot P_i}{n} \cdot K_1 = \frac{9550 \cdot 30}{8} \cdot 1,8 = 64462 \text{ Nm}$$

1.2 Based on consumed power (P_c)

First calculate the drum static pull (F_p):

$$F_p = \frac{Q + G}{i_r \cdot K_2} = \frac{300000 + 10000}{4 \cdot 0,95} = 81579 \text{ N}$$

Table n.º 3.
Conversion table

1 mm	0,0394 inch
1 inch	25,4 mm
1 m	39,4 inch 3.283 ft
1 kg	2,2046 lb (weight)
1 lb (wt)	0,4536 kg
1 N	0,2248 lbs (force)
1 lb (f)	4,4482 N
1 Nm	0,7376 lb-ft
1 lb-ft	1,3558 Nm
1 kgm	23,76 lb-ft
1 lb-ft	0,1382 kgm
1 kW	1,34 HP
1 HP	0,746 kW

And with the drum lifting speed rate (V_r):

$$V_r = \pi \cdot D \cdot n = \pi \cdot 0,8 \cdot 8 = 20,1 \text{ m/min}$$

Consumed Power of the motor (P_c) is calculated:

$$P_c = \frac{F_p \cdot V_r}{60000} = \frac{81579 \cdot 20,1}{60000} = 27,3 \text{ kW}$$

And then the Torque:

$$T = \frac{9550 \cdot P_c}{n} \cdot K_1 = \frac{27,3 \cdot 9550}{8} \cdot 1,8 = 58660 \text{ Nm}$$

Worst case of 1.1 and 1.2 is 64462 Nm, coupling maximum permissible Torque $T_{c \text{ MAX}}$ must be over this value.

With this requirement, minimum size of coupling is TCBR - 500 with a value of 102600 Nm.

2. COUPLING ADMISSIBLE RADIAL LOAD F_r

With the layout like Fig. 10, equation number 7 is required for the Radial Load:

$$F = [F_p (1 - \frac{b}{l})] + \frac{W}{2} =$$
$$[81600 (1 - \frac{400}{1200})] + \frac{14000}{2} = 61400 \text{ N}$$

Since the TCBR – 500 can withstand a radial load F_r of 133400 N and is over the calculated 61400 N, the selection is correct.

2.1 CORRECTED RADIAL LOAD F_A

If there is a case where the calculation required radial load F is over the coupling admissible radial load F_r , prior to select a bigger coupling, there is a chance of doing a calculation for the Corrected Radial Load F_A . using equation 8:

$$F_A = F_r + \frac{[(T_{c \text{ MAX}} - T)]}{K_1}$$
$$[133400 + (102600 - 64462) / 1,8] = 154588 \text{ N}$$

So, in this case the coupling will be able to withstand a radial load F up to 154588 N.

3. CONNECTION BETWEEN COUPLING AND SHAFT

Last step is to check shaft connection.

Maximum allowed diameter for TCBR – 500 coupling is 215mm, since the shaft diameter is 200mm, selection is correct. This maximum bore is for an execution with keyways according to DIN 6885/1, for other type of connections validation of torque transmission must be performed.

TCBRA WITH LIMITED AXIAL TRAVEL

For special layouts where no axial limiting bearing can be used in one side of the drum, it is required the use of special coupling design doing the bearing job. An example is a crane lifting layout where the drum is driven from both sides, in one side standard Barflex® TCBR coupling is used but in the other side, the special TCBRA design is required replacing the bearing and avoiding axial oscillations.

Barrel coupling TCBRA is not designed to support axial load. For each size, there is a maximum value that the coupling can withstand:

F _A MAXIMAL AXIAL LOAD (kN)		
SIZE	MAX AXIAL LOAD	d MAX (KEYED CONNECTION)
TCBR	kN	mm
200	60	135
300	65	150

WEAR INDICATOR

One big advantage of barrel couplings compared to other types of couplings is the ability to perform preventative maintenance using a wear indicator. The design of barrel couplings allows them to tolerate a greater amount of wear without appreciable decrease in operating capacity, which makes it possible to more easily monitor wear.

Although some manufacturers provide wear indicators for gear couplings, the small amount of wear allowed for this type of coupling makes them unreliable and overly complex to use for preventative maintenance purposes.

The amount of wear in the barrel coupling can be inspected by comparing the location of the pointer which is mounted on cover with respect to the edges of the indicator pin mounted on hub, as shown in Figure 14.

When this Pointer edge, reaches to either of the edge of indicator pin, then it is the time to replace the coupling.

Recommended wear limit values (m/2) are found in Table n.º 6.

The recommended wear limits shown in Table n.º 6 are for applications in which the load is applied in only one direction (example: crane hoists). In the case where the coupling is loaded in both directions (examples: travelling, looper cars in steel mills), then the recommended wear limits are HALF the values shown in Table n.º 6. Unless otherwise specified in the customer's order, the wear indicator marks on the coupling will be equal to the values shown in Table n.º 6.

Table n.º 6. Control of coupling wear

Coupling size	25	50	75	100	130	160	200	300	400	500	600
Max. wear m/2 [mm]	4	4	4	4	6	6	6	6	6	8	8
Coupling size	1000	1500	2100	2600	3400	4200	6200	8200	9200	10200	
Max. wear m/2 [mm]	8	8	8	8	8	8	8	8	8	8	8

Without Wear

Maximum Wear

Wear position

ELECTRONIC WEAR INDICATOR IN HOISTING SOLUTION

An electronic wear indicator feature is also available on demand. This feature allows the user to monitor wear remotely. So, in addition to the visual wear indicator, an electronic wear indicator can be connected either to the operator's control system or to an optional display unit to allow continuous or periodic monitoring of the barrel coupling wear.

Fig. n°. 15.
Electronic indicator

- Real time wear indicator: shows real progressive wear magnitude against wear limit.
- Reliable and accurate wear value, even in max. misalignment working conditions.
- Gives alarm once max. wear limit is reached.
- Can give direct signal to crane PLC.
- Can be placed inside crane control panel.
- In very dusty working atmosphere positively tested.
- Operating temperature from -15°C to 60°C.

SHAFT CONNECTION TYPES

*SAFESET is believed to be the trademark and/or trade name of Voith Turbo Safeset AB, and is not owned or controlled by Regal Beloit Corporation.

RECOMMENDATIONS FOR SHAFT/BORE FITS

The following recommendations, according to ISO, are given for shaft/bores fits.

TYPE OF FIT	SHAFT TOLERANCES	BORE TOLERANCES
INTERFERENCE FITS WITH PARALLEL KEYWAY	h 6	S 7
	k 6	M 7
	m 6	K 7
	n 6	J 7
	p 6	H 7
SHRINK FITS* WITHOUT PARALLEL KEY	u 6	H 7
	v 6	
	x 6	

* The stresses on the hub must be checked.

For other types of connection, please consult our Engineering Department. For one keyway, a keyway tolerance width ISO P9 is recommended. For double keyway, ISO JS9 is recommended.

GLOBAL PRESENCE

MANUFACTURING FACILITIES & ENGINEERING CENTERS

JAURE® & KOP-FLEX® engineered couplings are designed, manufactured, sold and serviced worldwide, with service provided from specification right through to installation.

Facilities around the globe are state of the art, with access to a large and experienced engineering staff focused on providing solutions for our customers' requirements.

A dedicated global sales and service team assists you to find the best choice and manage all your coupling needs.
